A FIGURE IS WORTH A THOUSAND WORDS: THE ROLE OF VISUALIZATION IN PARADOX THEORIZING.

Abstract

Visualization (i.e., the use of figures and images to represent findings and conceptual models) is central to theorizing. Yet, by focusing solely on the textual content of papers, analysis has inadvertently marginalized the graphic representations of key ideas. We review the paradox literature not just in terms of what authors have written but also how they have visualized models concisely. An analysis of figures in paradox articles captures the essential role that visuals play in our understanding of competing tensions, leveraging the power of imagery. We explore paradox *visually*, searching for the figurative materialization of paradox; more particularly, we seek visual signs that render abstract ideas more saliently and concretely. We contribute to paradox theory in three ways. First, we show how visuals constitute the lynchpin between convergent and divergent forces, allowing scholars to simultaneously reinforce and challenge current understanding. Second, we offer a tool for scholars to theorize competing demands based on three key antinomies, or dualities, that define the terrain of research in our field. Third, we reveal the performative effect of figures by identifying the ongoing dominance of certain classes of paradox visuals, which allows us to point to uncharted territories for paradox research.

KEYWORDS: paradox theory, visual analysis, visual representation of paradox, semiotics, theorizing.

Introduction

Paradox is central to management and organization scholarship if only because tension and opposition are an inherent part of organizational practice (Putnam, Fairhurst, & Banghart, 2016; Schad, Lewis, Raisch, & Smith, 2016). Dynamic expressions of paradoxical balance are evident in various analyses of proliferating contradictions between multiple logics in organizations and in society (Carmin et al., 2021). Paradoxes have been described as “contradictory yet interrelated elements—elements that seem logical in isolation but absurd and irrational when appearing simultaneously” (Lewis, 2000, p. 760). Paradox theory addresses diverse challenges arising from individual or group tensions (Berti & Simpson, 2021a; Pamphile, 2022; Pradies et al., 2021a) to global challenges (Sharma et al., 2021). Paradox is an umbrella concept covering multiple facets, including dynamic expressions of paradoxical balance, as are typically assumed in the *both-and* approach, as well as lack of balance, as in stuckedness-circularity and dialectical transformation. The development of the field has been both convergent and divergent (Schad, Lewis, & Smith, 2019). Centripetal forces foster theoretical convergence around core concepts, while centrifugal forces push the field’s boundaries (Hahn & Knight, 2021b) through interdisciplinary innovation. Both dynamics are “vital to the development of paradox theory” (Schad et al., 2019, p. 108). Despite their interrelated nature, their binary conception minimizes theoretical convergence (Cunha & Putnam, 2019), revealing limits to understanding paradox, as Schad et al. (2019) note. A vibrant cross-disciplinary intellectual community of paradox scholars has emerged, employing a variety of methods to address a wide array of topics (Putnam et al., 2016; Schad et al., 2016; Berti & Cunha, 2022), tensions and their management (Schad et al., 2019; Keller et al., 2021).

Visuals are an effective channel to convey paradoxes (Halgin, Glynn, & Rockwell, 2018; Vince, 2021; Vince & Broussine, 1996), with specific visuals, exemplified by the widespread use of the yin-yang symbol (e.g., Smith & Lewis, 2011), being widely associated with the concept. Figures are constitutive

1
2
3 of the core messages presented in many academic papers (particularly those dealing with complex
4 issues). Rather than being mere embellishments, they complement written text and concepts, offering
5 an illustration of the phenomena researched as well as the conceptual frameworks explaining their
6 causes, dynamics, and consequences.
7
8
9
10

11
12
13 A rich tradition in visual organizational research has shown (e.g., Quattrone, Ronzani, Jancsary, &
14 Höllerer, 2021) that visuals serve multiple purposes. First, visuals have a strong performative effect
15 when they orient our attention to what counts and what is legitimate in the literature (Meyer, Höllerer,
16 Jancsary, & Van Leeuwen, 2013; Quattrone et al., 2021), thus shaping theorizing. Second, conceptual
17 depth is increased when scholars and their audiences gain insight not immediately communicated by
18 textual exegesis (Avakian, 2020). Visualization facilitates aesthetic communication of highly abstract
19 concepts (Ravasi, 2017). Hence as Messaris and Abraham (2001, p. 225) state, “pictorial framing is
20 worthy of investigation not only because images are capable of conveying un verbalized meanings, but
21 also because awareness of those meanings may be particularly elusive.” Finally, visual devices are
22 powerful and effective communications for building academic–practitioner bridges (Trumbo, 1999).
23 The use of well-known visuals, including symbols that have deep historical roots and wide global
24 awareness, such as the yin-yang symbol, serve diverse traditions in contextualizing universal human
25 experiences (Lindgreen & Maon, 2019).

45 In this article we asked the broad question: How do visuals in paradox academic work address the
46 tension of convergence and divergence in paradox theorizing, focusing on (1) what do visual
47 representations in paradox academic work reveal about paradox and its assumptions and (2), what new
48 possibilities and areas of exploration does mapping the literature reveal? Our analysis contributes to
49 paradox theory in three ways. First, we show that visuals constitute the lynchpin between convergent
50 and divergent forces, allowing scholars to simultaneously reinforce and challenge current
51 understandings of paradoxes. Second, we put forth a theorizing tool that defines the terrain on which
52
53
54
55
56
57
58
59
60

1
2
3 paradox research has been built and identifies three antinomies, or dualities, as the cardinal points.
4
5 Third, we reveal the performative effect of visuals by identifying a few classes that have dominated the
6
7 imagery used in paradox research, and we subsequently draw attention to classes that reflect uncharted
8
9 territories in the field.
10
11

12
13 We structure our paper as follows. We briefly outline the trajectory of paradox theory, presenting the
14
15 opportunities offered by examining the use of visuals as a core component of theory development and
16
17 communication. Building on a comprehensive review of the literature on paradox, we identify the basic
18
19 visual grammar used in figures published in influential academic journals and relevant book chapters.
20
21 Moving iteratively between this basic visual lexicon and that of narrative text, we inductively identify
22
23 three fundamental antinomies – equilibrium/disequilibrium, linearity/recursivity and
24
25 boundedness/openness – that allow us to map alternative conceptualizations of paradox. From the eight
26
27 possible combinations (or “classes”, as we name them in the Findings’ section) of these three
28
29 antinomies, we derive an exhaustive typology associated with essential iconic representations in
30
31 paradox theory. While our analysis focuses exclusively on visualization in scholarly works, it allows
32
33 us to identify conceptual undercurrents shaping the evolution of theory as well as areas requiring further
34
35 investigation. Finally, we discuss the implications of our findings for future research and practice.
36
37
38
39
40

41 42 **Paradox theory: rich in reflexivity, yet blind to the use of visuals**

43
44

45
46 Scholars and philosophers have speculated on paradox for centuries. In management studies, analysis
47
48 of persistent opposite and interrelated tensions started with the contributions by Quinn and Cameron
49
50 (1988), Poole and Van de Ven (1989) and Lewis and Smith (Lewis, 2000; Lewis & Smith 2014; Smith
51
52 & Lewis 2011). Subsequent years have seen a significant increase in scholarly research on paradox
53
54 (Schad et al., 2016) which, of late, has grown exponentially (Cunha & Putnam, 2019; Fairhurst, 2019).
55
56 Scholars from various disciplines, working with different methodologies (Putnam et al., 2016; Schad
57
58
59
60

1
2
3 et al., 2016, 2019), contribute to “conversations on a shared objective – understanding organizational
4 tensions and their management better” (Schad et al., 2019, p. 108).
5
6

7
8
9 Scholars seek to strengthen paradox theory by refining definitional clarity (Smith, 2014; Smith &
10 Lewis, 2011; Berti & Cunha, 2022), identifying central concepts of opposition, interrelation,
11 persistence, and undecidability, as well as differentiating paradox from dilemmas, dialectics, or
12 dichotomies (Putnam et al., 2016). Some have analysed key processes at the heart of paradox dynamics,
13 such as vicious and virtuous cycles (Pradies, Tunarosa, Lewis, & Courtois, 2021b; Sundaramurthy &
14 Lewis, 2003), or provided reflection on paradox’s either inherent or socially constructed nature through
15 insights on the salience or latency of paradox (Hahn & Knight, 2021a; Pradies, 2022; Schad & Bansal,
16 2018). Not only have responses to paradoxical tensions been widely discussed (Jarzabkowski & Lê,
17 2017; Jarzabkowski, Lê, & Van de Ven, 2013) but also emphasized the need to work through paradoxes
18 (Lüscher & Lewis, 2008; Pamphile, 2022; Pradies et al., 2021b) to find a balance between integration
19 and differentiation (Cunha & Putnam, 2019; Smith 2014). Lewis and Smith (2014) recognize paradox
20 theory and its multifaceted uses as a metatheory. Schad and colleagues (2019, p. 108) describe
21 centripetal forces reinforcing core elements of the theory, while centrifugal forces have “pull[ed] away
22 from the core to spur exploration and creativity, challenging, spanning, and extending its boundaries.”
23 By demonstrating the role of power dynamics in generating pragmatic paradoxes (Berti & Simpson,
24 2021a), or by exploring questions of disequilibrium (Hargrave, 2020; Hargrave & Van de Ven, 2017),
25 researchers have expanded paradox scholarships’ theoretical boundaries.

49 Paradox scholars’ dialogues in *Academy of Management Review* between Li (2021b) and Berti and
50 Simpson (2021b), and Li (2021a) and Hahn and Knight (2021a) capture the vibrancy of current debate.
51 “[P]aradox scholars ‘agree to disagree,’” fostering “conflicting yet interdependent views on key
52 concepts that co-exist and energize community debates” (Schad et al., 2019, p. 110). The paradox
53 scholarship research program’s use of language, research craft, thinking style, and use of material tools
54
55
56
57
58
59
60

1
2
3 underpinning theorizing (Clegg, Cunha, & Berti, 2022) displays a vitality that invites further inquiry.
4
5 To ensure that the vitality of divergent efforts counterbalances too much convergence (Cunha &
6
7 Putnam, 2019), both centripetal and centrifugal efforts are essential to “surface and open the remaining
8
9 ‘black boxes’ of paradox theory” (Schad et al., 2019, p. 108).
10
11

12
13 Visual representation of the findings or conceptual contributions presented characterise many works
14
15 published in the field; indeed, visuals have been integral to the evolution of paradox theory. A
16
17 foundational work by Vince and Broussine (1996) relied on drawings to articulate the paradoxes that
18
19 managers faced in the wake of organizational change, while the yin-yang symbol was used by Lewis
20
21 (2000) and Smith & Lewis (2011). Such visualizations capture holistic and simultaneous forms of
22
23 signification that are difficult to express but essential for a better understanding of the notion of paradox
24
25 (Halgin et al., 2018).
26
27
28

29
30 While visuals characterize key contributions, they are rarely the focus of attention, a surprising blind
31
32 spot, as visuals enable researchers to capture the ineffable absurdity (Lewis, 2000) and logic-defying
33
34 dynamics sometimes present in interrelated contradictions. Visualization assumes different roles (Berti,
35
36 2017), with Gibson (1978) noting that depiction frames description, meaning that how an object, such
37
38 as a paradox, is represented visually inscribes interpretation of its meaning. For Gibson (1978, p. 233),
39
40 “depiction captures an awareness without describing it.” We see visualizing as central to the theorizing
41
42 process, able to generate novel theories, as suggested by the visual turn in management studies (Meyer
43
44 et al., 2013; Quattrone et al., 2021; Swedberg, 2016). Editors and reviewers pay great attention to the
45
46 consistency between text and figures (Fulmer, 2012). Even if one accepts that “diagrams are not theory”
47
48 (Sutton & Staw, 1995, p. 376), figures and other visuals, together with textual headings and
49
50 propositions, are essential in conveying the essence of academic work (Lange & Pfarrer, 2017). Not
51
52 only do visuals help clarify other inscriptions but they also provide formal models that allow assessment
53
54
55
56
57
58
59
60

1
2
3 of the “balance between parsimony and completeness” in a theoretical contribution (Whetten, 1989, p.
4
5 491).

6
7
8
9 Ravasi (2017, p. 243) suggests that visualizing qualitative data is essential to solving the “mystery of
10
11 theorizing from qualitative data.” Similarly, Parmentier-Cajaiba and Cajaiba-Santana (2020) argue that
12
13 visual mapping enables researchers to engage with data by selecting, removing, or adding elements, as
14
15 a steppingstone in the theorizing process. Visualizations allow researchers to theorize without being
16
17 “bound by convention or preconceived notions of linear cause and effect” (Langley & Ravasi, 2019, p.
18
19 188). Images have narrative power (Kassinis & Panayiotou, 2018); they embed knowledge (Ewenstein
20
21 & Whyte, 2009), bringing new meaning to textual understanding.
22
23
24
25

26
27 In sum, visuals are central to knowledge production (and dissemination) processes (Quattrone et al.,
28
29 2021; Meyer et al., 2013). Indeed, many scholars, noting the performative function of visuals (e.g.,
30
31 Meyer et al., 2013; Steyaert, Marti, & Michels, 2012), observe “how visualization practices produce
32
33 organizational outcomes” (Quattrone et al., 2021, p. 1197), such as theorization. Visualization frames
34
35 what is seen as worthy (Arjaliès & Bansal, 2018), not only facilitating sensemaking but also mobilizing
36
37 actors’ (and “spectators’) attention. In addition, it may be used as a means for contestation (Kornberger,
38
39 2017). As such, visualization not only defines appropriateness but also offers opportunities to debate
40
41 what is worthy of attention by establishing “arenas for performance” (Quattrone et al., 2021, p. 1205).
42
43
44
45

46
47 To sum, we will investigate how visuals in paradox theorizing work to address tensions of convergence
48
49 and divergence. In particular, we focus on two questions: (1) what do visual representations in paradox
50
51 academic work reveal about paradox and its assumptions, and (2), what new possibilities and areas of
52
53 exploration does mapping the literature reveal?
54
55
56
57
58
59
60

Methodology

Tracking visuals in organizational paradox theory

We analyse the use of visuals in paradox theorizing in the published literature to study the use and impact of graphic representations in constituting the corpus. We selected 193 papers containing 266 figures, in a sequence of four steps from the core literature. First, we used a systematic analysis of the organizational paradox literature that considered all peer-reviewed works published in the last four decades following the method employed by Schad et al. (2016). We surveyed Web of Science for articles with the word ‘paradox’ in their titles, abstract or keywords, between 1980 and 2021; this resulted in over 93,000 articles. We then narrowed the focus to business and management and excluded book reviews, meeting abstracts, proceedings papers and editorial material. Finally, we filtered the results, based on research quality, by selecting journals with a 5-year impact factor of at least 2.00 in 2020 (according to the *Journal Citation Reports*). Next, we searched for articles citing at least one of four foundational works on paradox in the management literature by Quinn and Cameron (1988), Poole and Van de Ven (1989), Lewis (2000), and Smith and Lewis (2011). Focusing on these works ensured focusing on studies consistently applying a paradox lens, creating a community of practice. While different levels of engagement with paradox theory characterize papers in the sample, use of paradox as an umbrella concept is common. We also added relevant book chapters (n=40) and forthcoming articles in 2021 (n=25) as well as articles that drew heavily on paradox theorizing and were cited by paradox scholars (e.g., Ashforth & Reingen, 2014) but lacked paradox in their keywords, title or abstract. We added articles that appeared in journals with an impact factor below 2.0 that were often cited (e.g., Abdallah, Denis, & Langley, 2011), creating a total population of 433 academic works.

A total of 193 papers (79 conceptual and 114 empirical) used visual figures representing paradoxes or tensions. We identified a total of 266 unique figures by excluding figures representing statistical analysis, hypothesised relations among variables, or images used as empirical material with no

1
2
3 reference to paradox. We coded these figures by distinguishing images describing types of
4 tensions/oppositions (n=136) from images representing/conceptualizing paradox dynamics (n=129).
5
6 While half of the initially sampled papers did *not* contain visual figures, our findings are not
7
8 constrained in terms of their generalizability as a separate corpus of literature, founded on different
9
10 conceptual assumptions, if only because they are frequently cited in the ‘nonvisual’ articles. Therefore,
11
12 our sample provides indications about the direction and debates in the paradox literature.
13
14
15
16
17

18 *Coding the visual representation of paradox: a classificatory device*

19
20
21 **Step 1. Identifying the basic lexicon of paradox visualization.** Our analytical process was nonlinear
22 and iterative between data and theory (Strauss & Corbin, 1998); however, for readability, we describe
23 it as a series of sequential steps (illustrated in Figure 1). Once our corpus of 193 academic works and
24 266 figures was identified, two co-authors began inductively coding the first 150 figures to develop a
25 consistent approach to ‘breaking down’ complex models into basic forms in a process akin to open
26 coding (Strauss & Corbin, 1998). The purpose was to break down figures into more accessible,
27 interpretable objects, focusing on their essential elements, i.e., the elementary symbols used to
28 compose them.
29
30
31
32
33
34
35
36
37
38
39

40
41 While visual representations can be analysed in different ways, considering their representational,
42 interactional, and compositional meaning (Kress & Van Leeuwen, 2020), we focused on recurring
43 symbols. Basic signs were analysed in a manner akin to ‘word frequency analysis’ in critical discourse
44 analysis. The method allows identification of general assumptions or trends in a particular textual
45 corpus; for example, it can show how positive or negative ideas are associated with a particular object
46 (Bednarek & Caple, 2014). We identified some essential basic signs: boxes, arrows, straight and
47 curved lines. We selected frequently found combinations of these basic signs consistently conveying
48 specific meanings: different types of straight lines with arrows (one-directional, bi-directional,
49 converging, diverging, zigzag), bounded annular shapes (circles, loops, knots), spirals, triangles, steps
50
51
52
53
54
55
56
57
58
59
60

1
2
3 and cartesian diagrams. The two co-authors performed the operation individually and then discussed
4
5 and resolved ambiguities. In this way, they treated visual representations as any other form of
6
7 signification, enabling the communication of complex ideas through the combination of a conventional
8
9 set of elements (a visual repertoire, that comes together in more complex patterns). They also identified
10
11 several images that need to be considered holistically, such as yin-yang, scale, bridge, cloud, waves,
12
13 etcetera.
14
15

19

20
21 Figure 1 about here
22
23
24
25 -----
26
27

28
29 **Step 2. Identifying and refining antinomies to make sense of the basic lexicon.** Going back and forth
30
31 between data and theory, and expanding our coding to the other figures, some of the basic elements of
32
33 our visual lexicon emerged in an iterative process. Akin to a process of axial coding (Figure 1) as
34
35 suggested by Strauss and Corbin (1998), we explored relationships among groups of basic visuals,
36
37 iterating back and forth between data analysis and the literature the better to understand emerging
38
39 themes and group the basic elements. Initially, we surveyed the paradox literature and identified
40
41 relevant concepts at the heart of paradox depiction. In doing this, we mirrored methods of discourse
42
43 analysis that are based on the frequency of types of words (e.g., Tausczik & Pennebaker, 2010).
44
45 Inspired by the fundamental assumption of paradox theory, the idea that social organization is
46
47 invariably characterized by interdependent contradictions, we tried to identify opposite pairs that could
48
49 be used to typify the meaning of these basic symbols. In so doing, we identified various fundamental
50
51 contrasting dualities or antinomies. Antinomies, defined as pairs of concepts with opposite meanings,
52
53 constitute a typical device to organize knowledge; they are a primal determinant of those competing
54
55 tensions that paradox theorists explore (Keller & Chen, 2017). Using opposing pairs of concepts to
56
57
58
59
60

1
2
3 codify meaning in paradox scholarship constitutes an effective way of representing convergent or
4
5 divergent currents (Schad et al., 2016) (see Table 1 for our definition of antinomies). We came up with
6
7 three pairs: equilibrium/disequilibrium, open/bounded, and linearity/recursivity. These ideas capture
8
9 fundamental meanings conveyed by different symbols aligned with debates in the paradox literature,
10
11 as well as the organizational literature more broadly, as we will highlight in our findings.

25

26 Antinomies emerged as we iterated between data and theory. Some alternative antinomies were
27
28 considered (e.g., flux versus static) and then discarded because they were ambiguous or redundant
29
30 when it came to making sense of our basic sign lexicon. The whole team were involved in refining and
31
32 populating the emerging classification device (Table 2). Discussions on disagreements helped refine
33
34 our typology. Moreover, the six polar elements composing the three selected antinomies can be
35
36 unequivocally associated with specific graphic signs. For instance, circles are a clear representation of
37
38 recursivity, while straight lines and arrows are eponymous of linearity. Similarly, signs representing
39
40 openness (e.g., steps) suggest open systems with no defined boundaries and no predictable ends, while
41
42 signs representing boundedness (e.g., cartesian diagrams) evoke bounded systems and a predictable
43
44 end. Finally, some images (e.g., knots) are associated with stable balance, while others (e.g.,
45
46 pendulum) suggest the potential for instability and disequilibrium because of exogeneity. Some signs
47
48 provoked questions; for example, we had originally positioned the scale as a sign of disequilibrium
49
50 but not if the scale was “balanced”. We thus differentiated between the balanced scale (=equilibrium)
51
52 and the unbalanced scale (=disequilibrium). Similarly, we first considered cartesian diagrams as closed
53
54 but subsequently realized that arrows in cartesian diagrams may signify openness; despite this, in most
55
56
57
58
59
60

1
2
3 cases we categorized cartesian diagrams as bounded (e.g., in Ashforth, Rogers, Pratt, & Pradies, 2014
4 or Besharov & Smith, 2014). Raisch, Hargrave, and van de Ven (2018) offered a rare example of
5
6 arrows signalling openness in a cartesian diagram, reinforced by the existence of an additional arrow
7
8 at the end of the graph.

22
23

24 **Step 3. Synthesizing themes into aggregate theoretical dimensions.** Then, we sought to understand
25
26 the connections between the themes that made up the antinomies and theorize their interrelations
27
28 (Whetten, 1989) by engaging the paradox literature. We realized that the equilibrium/disequilibrium
29
30 antinomy spoke to the consequence of tensions (and responses to them), while the bounded/open
31
32 antinomy pointed to the evolution of these tensions and linearity/recursivity to their dynamics.
33

34
35
36 **Step 4. Outlining and refining an emerging classification device thanks to the three antinomies.** The
37
38 choice of these three antinomies enabled development of an exhaustive typology to categorize all the
39
40 visual signs (or basic elements) included in the works we examined, covering different phases of
41
42 paradoxes. By combining these three pairs we developed a typology of 8 possible classes, in which we
43
44 have collocated the 30 basic figures (see Figure 2). All elements of imagery, including complex images
45
46 that could not be broken down in their constituent components (e.g., the picture of the bridge, as
47
48 opposed to the boxes and arrows in a model), have been associated to one of the categories that result
49
50 from the combination of the opposites present in the three antinomies. Once the classificatory device
51
52 was refined, disagreement between the authors coding the images independently dealt with how to
53
54 ‘decompose’ a complex picture, including multiple signs, rather than how to ‘pigeonhole’ a single
55
56 visual element. For example, we had to interpret how to code a loop incorporating arrow signs; after
57
58
59
60

1
2
3 discussion, we agreed that the presence of the loop superseded the arrow, reinforcing the circular flow
4 without suggesting linearity. Only when an arrow emerged out of the loop, was it coded as a separate
5 element. All attempts at organizing reality through typologies (Cornelissen, 2017) create a vivid but
6 necessarily artificial separation. Ours were ordered by using the well-known typological device of the
7 two-by-two matrix (Lowy & Hood, 2004). The classic two-by-two diagram was enriched by the
8 inclusion of a third dimension (linearity vs. recursivity), allowing ordering and placing in relation to
9 alternative symbols that can be used to describe paradoxes without bundling in the same category
10 visual representations that are semantically distinct.

30
31
32

33 **Step 5. Classifying all elements in the classification and making sense of it.** We counted how many
34 of these constitutive elements were present in each academic work, looking at the use of different
35 classes of signs. Note that we conducted our analysis per figure. Thus, academic work including a
36 single figure composed of heterogeneous signs (i.e., belonging to different classes) was coded for
37 several classes. Similarly, because we conducted our analysis per number of figures, academic works
38 including two figures composed of homogeneous signs would be coded twice. If multiple signs
39 belonging to the same class (e.g., multiple arrows) were present in the same figure, they were counted
40 only once. Table 3 illustrates the frequency of appearance of each class of basic forms. Finally, we
41 considered how each type of sign featuring in a figure contributed to the three antinomies: for instance,
42 a yin-yang sign was counted as representing ‘equilibrium’, ‘boundedness’ and ‘recursivity’. For a
43 detailed overview of the coding per figures, please see our online appendix.

10 We addressed variance in classification depending on whether the article was empirical or conceptual;
11 whether the article represented paradox dynamics (i.e., focused on describing how a paradox evolves)
12 or paradox description (i.e., focused on describing a paradox).¹ The results presented in Table 4
13 suggested little variation between empirical and conceptual articles, with more variation between
14 articles representing paradox dynamics or paradox description. Using this method, visual discourse
15 analysis revealed evolutionary directions in paradox literature as well as less frequent areas of
16 discussion (in relation to the three fundamental concerns identified by the aggregate theoretical
17 dimensions).

40 **Findings: the antinomies**

41
42
43 The first antinomy that surfaced is equilibrium versus disequilibrium (Cunha & Putnam, 2019). When
44 facing competing demands, this pair represents opposite tendencies to (1) find balance and synergy,
45 while preserving the status quo (Smith & Lewis, 2011) or to (2) recognize the state of constant
46 imbalance brought about by oppositions that are interrelated, as well as how opposite tendencies are
47 constantly in flux, disrupting the status quo (Hargrave & Van de Ven, 2017). The tension between the
48
49
50
51
52
53
54
55

56 ¹ To differentiate between the two, we used the caption of the figure to confirm our understanding of the depiction. For
57 example, figures with titles mentioning “process”, “dynamics”, “effects”, “cycles/circles” and more in general mentioning
58 actions (gerund verbs), were categorized under the category “paradox dynamics.” We instead coded as “paradox
59 description” figures which captions mentioned typology, paradox type, static oppositions. We also included in this category
60 figures in which the presence of a verb in the caption did not refer to the paradoxical phenomenon represented.

1
2
3 ‘orthodoxy’ that privileges a symmetrical and hence power-neutral view of paradox (Van Bommel &
4 Spicer, 2017) and studies that highlight asymmetry within opposite pairs and the intertwining of
5 paradox and power is also represented (Berti & Simpson, 2021b; Gaim, Clegg, & Cunha, 2021).
6
7
8
9
10 Equilibrium/disequilibrium is a key tension in analysis of economic policy interventions as well as a

Equilibrium/disequilibrium is a key tension in analysis of economic policy interventions as well as a foundational tension in structural functionalist theory (Parsons, 2013). Conveyed through signs such as the pendulum (i.e., disequilibrium of stasis) or overlapping circles (i.e., equilibrium), this antinomy was particularly relevant in representing paradox processes. In our analysis, equilibrium refers to a sign that points to balance and symmetry between opposites, leading to stable outcomes. By contrast, disequilibrium describes a sign that suggests imbalance and asymmetry between opposites, leading to outcomes other than stasis.

The second antinomy, open versus bounded, captures the problem of considering paradox concisely in the perspective of a bounded or open system (Schad & Bansal, 2018). Such an opposition points to the problem of studying paradox at multiple levels (Berti, Simpson, Cunha, & Clegg, 2021; Gotsi, Andriopoulos, Lewis, & Ingram, 2010), as nested and interwoven (Andriopoulos & Lewis, 2009; Cunha, Simpson, Clegg, & Rego, 2019). The degree of boundedness/openness, particularly relevant in looking at paradox processes, is the key tension in systems theory of organizations (Scott & Davis, 2015). Open system epistemology emphasizes how paradox interacts with other elements of organization; open-endedness occurs because of the ontological unfolding and indeterminate nature of the world and its events (Hadjimichael & Tsoukas, 2019), stressing paradoxes’ constant evolving. By contrast, a bounded system approach tends to focus on systems that are isolated from their environment, emphasizing paradox as a self-contained occurrence (Tsoukas & Cunha, 2017), an antinomy captured in visual circles and zigzags. More globally, we use the attribute ‘open’ to describe a sign that suggests a divergent process in which outcomes are indeterminate, without a defined end, or a system whose boundaries are not set. By contrast, being ‘bounded’ refers to a process that is convergent, with a predictable end or a system which is self-contained and immanent.

1
2
3 The third antinomy, recursive versus linear, represents the tension between the need to signify
4 paradox's distinctive epistemological foundations, characterized by the self-reproducing nature of
5
6
7
8 social phenomena (Hernes & Bakken, 2003), while managerial legitimacy strives for ways to 'break'
9
10 the vicious circles that paradoxicality generates, thus highlighting their practical transformative
11
12
13 potential (Smith & Lewis, 2011). Literature explores both the iterative ways in which interdependent
14
15
16 tensions self-reproduce, becoming persistent paradoxes (Schad et al., 2016) as well as the progression
17
18
19 from one step to another entailed in working through and transcending paradoxes (Abdallah et al.,
20
21
22 2011; Bednarek, Paroutis, & Sillince, 2017). A clear relation can be identified between paradoxes and
23
24
25 responses to paradoxes or steps to escape paradox (Pradies et al., 2021b). In positivist and
26
27
28 phenomenological accounts of causality in organizational analysis, it is linearity/ recursivity (Hernes
29
30
31 & Bakken, 2003; Meyer, 1972) that is at issue. Single arrows signify linearity while recursivity was a
32
33
34 recurrent theme in visuals with spirals. Signs that indicate a sequence of events that progress in a single
35
36
37 direction are linear; by contrast, signs that illustrate a process that iteratively loops into itself, leading
38
39
40 to virtuous or vicious cycles, highlight recursivity.

Findings: the evolution of paradox theory through visuals

The above-mentioned antinomies identify eight classes categorizing basic visual signs. One rule we constructed was not to consider individual shapes *per se* but clusters of 'similar' shapes identified by classification. The eight classes may be viewed as ways of seeing paradox as an umbrella concept, each portraying dimensions absent in the others. Below we expand on the eight classes identified, drawing on illustrative figures to exemplify our thoughts (also see the online appendix). As each figure may have multiple elements belonging to different classes, we tried to pinpoint figures in which the class in question is particularly striking.

Class #1. Balanced opposition (equilibrium – bounded – linear)

1
2
3 Class #1 emphasizes persistent oppositions in relative balance. The signs in this class often portray a
4 simple, clear, and static relationship between the elements of the model, which stand in symmetrical
5 opposition to one another. The tensions constitute a bounded system in which no outside forces have
6 an impact on the relationship among competing demands. The most common forms include
7 overlapping circles, cartesian diagrams or triangles, and other basic geometrical shapes. For example,
8 Bloodgood and Chae (2010) use a cube to capture several paradoxes that cultural organizations face in
9 promoting art, music, and entertainment. The opposing poles of each paradox (e.g., autonomy versus
10 control) are depicted as opposite corners of the cube. The authors theorize that organizations manage
11 paradoxes integratively as they move within the cube (from one corner to the other) to find equilibrium,
12 thus visually enabling the theorization of opposing forces within which there is movement and
13 adaptation.

17
18
19
20
21
22
23
24
25
26
27
28
29

30 Cartesian diagrams also emphasize persistent oppositions in relative balance since the interrelation
31 between both poles is only possible when considering the intersection of the axis opposition (Bansal,
32 Bertels, Ewart, MacConnachie, & O'Brien, 2012; Erdogan, Rondi, & De Massis, 2020). Tensions are
33 thus contained within ideal boundaries whose outcome is somewhat predictable, preserving the status
34 quo. Thus, movements and transformations are linear, in that the paradox follows a predefined path
35 along relatively predictable steps or phases. Two-by-two models, as used by Besharov and Smith
36 (2014) and Smith (2014), or the concentric circles and triangles employed by Engeström and Sannino
37 (2011), illustrate this class of balanced opposition. Sometimes these elements come as a background,
38 associated with 'dynamic' signs, as in the use of Cartesian coordinates which frame curves (Hahn,
39 Pinkse, Preuss, & Figge, 2015; Ofori-Dankwa & Julian, 2004). This class of signs were found in 27%
40 of the figures.

49
50
51
52
53
54
55

56 ***Class #2. Uncertain struggle (disequilibrium – bounded – linear)***
57
58
59
60

1
2
3 Similar to the visuals in class #1, this representation of paradox emphasizes a simple relationship
4
5 between forces in direct opposition. However, the visuals in this class underscore the intractable
6
7 struggle between forces and the process of imbalance that ensues. The struggle locks the system in its
8
9 own closed realm, isolated from the environment. While the visuals in this class do not necessarily
10
11 portray steps or phases, the relationship between the opposing poles prevents any form of recursivity
12
13 or virtuous dynamics as permanent struggle is represented. Commonly used visuals in this class include
14
15 arrows converging towards one point. In the sources we examined, arrows typically appear in
16
17 conjunction to show the interplay of forces caused by the paradox (e.g., Berti & Simpson, 2021a;
18
19 Langley & Klag, 2019; Pradies, Delanghe, & Lewis, 2020). For example, discussing the paradox faced
20
21 by middle managers, Pradies and colleagues (2020) middle managers are positioned between the top
22
23 management team and the followers, connecting them. The opposite arrows, stemming from the top
24
25 management team and from followers converging towards leaders, illustrate the leader/follower
26
27 paradox in which connecting leaders are both leaders to some and followers to others struggling to
28
29 meet opposite demands. Similarly, Langley and Klag (2019) use opposing arrows to theorize a constant
30
31 struggle for field researchers, who navigate the tension of personalizing their research by becoming
32
33 deeply involved with the subjects and elements of a particular research setting while depersonalizing
34
35 the research as required by academic protocols. Berti and Simpson (2021a) also use clashing arrows to
36
37 theorize how episodic and systemic powers underlie paradox dynamics in organizations. This class of
38
39 signs is present in 11% of the figures.
40
41
42
43
44
45
46
47

48 ***Class #3. Cyclical reproduction (equilibrium – bounded – recursive)***

49
50
51 The visuals in class #3 emphasize a recursive dynamic between tensions. That is, the visuals show
52
53 opposite forces defining and shaping each other in a repetitive process. Opposite forces are thus
54
55 simultaneously kept together and pulled apart in a cyclical reproduction critical for achieving stability.
56
57 The signs convey a sense of self-containment of a system isolated from its environment. Multiple signs
58
59
60

1
2
3 occur in this category, including bidirectional arrows, feedback loops, the yin-yang, the Janus
4 relationship, knots, interwoven patterns, etc. For example, Lewis and Dehler (2000) theorize the
5 control-flexibility paradox in the classroom by using a loop on top of a cartesian diagram. They draw
6 on the work of Johnson (1992), who emphasizes the need to understand oppositions and how opposite
7 poles interrelate, entrapped in a continuous and repetitive dance across positive and negative
8 dimensions of each pole. The loop highlights the infinite nature of this relationship and how it is only
9 by understanding the interrelation between the poles that one can navigate paradoxical demands. These
10 authors use the control-flexibility paradox whereby actors learn to value the positive dimensions of
11 focusing on control yet, if they focus on it, they may end up experiencing the negative dimensions of
12 control, namely extreme rigidity.
13
14
15
16
17
18
19
20
21
22
23
24
25
26

27 The loop suggests that to overcome the pitfalls of control, actors need to focus on its opposite pole:
28 namely flexibility, while being aware that too much flexibility can also result in negative outcomes. In
29 sum, this visualization represents theorizing opposites as they interrelate. The fact that the loop
30 highlights paradoxes occurring within a bounded system also highlights the persistent dynamics of such
31 interrelations. Slawinski and colleagues (Slawinski, Winsor, Mazutis, Schouten, & Smith, 2021) offer
32 a model for managing paradoxes regeneratively. The figure incorporates a feedback loop and bi-
33 directional arrows to suggest cyclical reproduction.
34
35
36
37
38
39
40
41
42
43
44

45 Paradox is represented as a dynamic process generating persistent repetitions (*ad infinitum*), in the
46 form of loops, knots (e.g., Sheep, Fairhurst, & Khazanchi, 2017) or cycles (e.g., Pradies et al., 2021b).
47 In such a view, analysis of paradox implies processes in their long-term dynamics. Viewing paradox
48 as a dynamic process highlights that systems dynamics may need to be explored over the long run,
49 with temporary adjustments being part of longer cycles. In this representation, persistency is a
50 consequence of the recursive dimension of paradox tensions, exemplified in the classic dynamic model
51 of organizing by Smith and Lewis (2011). It is this class of symbol that dominates the literature,
52
53
54
55
56
57
58
59
60

1
2
3 featuring in 58% of the figures. The dominance of the yin-yang was pervasive in anchoring the field
4
5 of paradox in a certain way.
6
7

8
9 ***Class #4. Oscillation (disequilibrium – bounded – recursive)***
10

11
12 The visuals in this class point to a recursive relationship between two elements, characterized by trade-
13
14 offs that maintain the system in disequilibrium, in constant imbalance, as any balance is only temporary
15
16 and precarious. These signs point to a bounded system, in that the elements are self-contained, limited
17
18 by how far from the middle point they diverge, evident in visuals of counterbalancing forces, images
19
20 of scales or a pendulum. Authors use the scale or other visuals from this class in two ways in their
21
22 theorizing. First, a swinging pendulum points to a constant lack of stasis within a bounded system with
23
24 recurrence of disequilibrium at the centre (see for example, Figure 3 in Lewis & Dehler, 2000). Second,
25
26 this sign is used to theorize either/or choices or dilemmas that paradoxes create and the related
27
28 vacillation of processing them, as in Smith and Lewis (2011), stressing either/or ways of thinking about
29
30 paradoxes. Smith and Lewis' (2011) example in a disequilibrium state (with one side heavier than the
31
32 other) aligns with our sensemaking of the class. Despite the subtleties offered by such signs, they are
33
34 extremely rare in our review, occurring in only 1% of the figures coded.
35
36
37
38
39
40

41 ***Class #5. Sequence (equilibrium – open – linear)***
42

43
44 The signs in this class suggest a sequential, continuous process in a system that may interact with its
45
46 environment because it is not bounded. These signs portray various straight arrows or sequences. They
47
48 abound in graphical representations in management studies. It is thus not surprising that 39% of the
49
50 figures coded included these signs, although it is not as dominant as class three (i.e., cyclical
51
52 reproduction). Scholars use this sign to theorize steps in a transformational process or a very simple
53
54 relationship, while allowing a connection with the environment. For example, Pradies and colleagues
55
56 (2021b) use this sign to highlight the steps of moving from vicious to virtuous dynamics. In their study
57
58
59
60

1
2
3 of plant purchasing managers (PPMs) entrenched in vicious dynamics at TradeCo, they chart the
4 progression that PPMs go through from vicious cycle, cycle break, cycle reversal, and virtuous cycle.
5
6 Other simple arrows are used to highlight the impact of the HR team on this process, showing how
7
8 such simple arrows allow for connections between those facing the paradox and supporting actors who
9
10 leverage the social-symbolic context. Similarly, Calabretta, Gemser and Wijnberg (2017) resort to such
11
12 arrows to present their three-step model of the intuition-rationality paradox, using them to convey the
13
14 progression of engagement with paradox that members of an innovating company experience along
15
16 with professional design processes.
17
18
19
20
21

22
23 ***Class #6. Chaotic change (disequilibrium – open – linear)***
24

25
26 The signs in this class suggest a sequential transformation that is not bounded, has no specified end,
27
28 and produces system instability. Common visuals in this class are divergent lines or arrows. There is a
29
30 lack of equilibrium that emerges from diverging lines or even from an image of a scribble or a cloud
31
32 (with no clear pattern). Paradoxical tensions are represented in this class of signs as change motors,
33
34 accentuating existing qualities/deficiencies in an organizational context. In this sense, the paradox
35
36 expresses a dynamic with inertial properties: the dynamics of paradox will accentuate pre-existing
37
38 inertial forces, deepening existing processes. A classic example of this effect is provided by the
39
40 tendency of successful organizations to repeat and reinforce past practices, leading to a simplification
41
42 that is functional (in the short term) while, in the long term, dysfunctional (Miller, 1993). There is one
43
44 main sign in this class, namely two arrows stemming from the same point and going in opposite
45
46 direction. Lewis, Welsh, Dehler and Green's (2002) article on tensions in product development
47
48 constitutes an example of such a sign used to theorize the notion of being torn apart, whereby the arrows
49
50 visualize the push of opposite management styles (emergent vs. planned) on the way in which product
51
52 development occur.
53
54
55
56
57
58
59
60

1
2
3 Examples of articles in this class also include Sharma and Good (2003), who depict tensions in a sharp-
4 edged cloud, while Lüscher and Lewis (2008) use a cloud that is softer edged. The authors use clouds
5 to highlight the workable certainty that Lego middle managers reach together with a consultant as they
6 work through paradoxical demands as well as to describe the messes that arise from the confrontation
7 with multiple paradoxes. The choice of cloud represents the constant shifting complexities of a dynamic
8 situation. Lüscher and Lewis (2008, p. 235) recognize the disorder tied to the changing reality that
9 accompanies the mess (represented by the cloud) but they also stress “a negotiated understanding,
10 sometimes even more complex than the former understanding, but eventually more meaningful and
11 actionable.” As a class of symbols this is neither rare nor is it one of the most frequently employed,
12 being featured in only 23% of the figures examined.
13
14

18
19
20
21
22
23
24
25
26

27 ***Class #7. Autopoiesis (equilibrium – open – recursive)***
28

29
30 The signs in this category point to the recursive relation between elements that lead to continuous
31 balance within an enclosed system, thereby preserving equilibrium. We use the term autopoiesis to
32 describe a system capable of reproducing itself by creating its own parts (Luhmann, 1995). The zigzag
33 is the sign that is found in this category, while the wave is the image. Tuckermann (2019) uses the wave
34 to theorize the oscillating nature of latency and salience. Smith and Besharov (2019) stress the
35 oscillating pattern between business and social mission undergone by the organization they studied.
36 They theorize an open recursive phenomenon with the breadth of the oscillation changing overtime,
37 while the oscillation is a repetitive figure. They thereby visualize and theorize a management of
38 paradox imbued with changing directions as the organization bumps against guardrails – presenting the
39 organization from drifting away from the paradox.

51
52
53

54
55 The category is extremely rare, accounting for only 1% of depictions. It is exemplified by a device
56 frequently used in lay literature to represent paradoxical situations but not yet employed in the paradox
57 literature, although it has been invoked by Orlikowski (1996) to study transformation. It is a class of
58
59
60

1
2
3 figures that exploits one idiosyncrasy of our visual system, the tendency to simplify visual scenes into
4 two distinct components: a figure in the foreground and a background containing everything else. If
5 the background has an intelligible shape, then it becomes possible to switch back and forth between
6 the perception of two different shapes, that constitute each other's background (M. C. Escher employed
7 this visual trick in some of his artworks). This type of symbology captures well the concept of
8 interdependence of opposites since figure and background require each other to be discernible and we
9 are forced in a loop as we attempt to capture both in our perception.

20 ***Class #8. Dialectic transformation (disequilibrium – open – recursive)***
21

22
23
24 The signs in this class show a recursive relation between opposing elements, which leads to a divergent
25 transformation that disrupts the existing system. The visuals in this class include: the spiral and the
26 helix, as well as escalation and cascade. The recursive relation suggested by these signs captures the
27 key idea behind 'disequilibrium'—that "balances are slightly imbalanced" (Kegan, 1982, p. 108).
28 When interpreted through a dialectic lens, the recursive relation could also portray the idea that a thesis
29 generates its own antithesis, before the clash of the two bring about a new thesis (synthesis) that will,
30 in turn, produce a new antithesis, in a continuous transformation, a permanent dialectic (Clegg &
31 Cunha, 2017; Clegg, Cunha, & Cunha, 2002). In this way, the signs in this class are critical to current
32 conceptualizations of paradox, for they convey, first, that finding balance across competing demands
33 is an ongoing struggle, and second, that this struggle repeats itself over time with increasing levels of
34 complexity. Hence, in their theorizing, paradox scholars who employ this class of signs tend to focus
35 on the mounting effects brought about by competing demands, especially when these constitute vicious
36 or virtuous cycles. An early example is Sundaramurthy and Lewis' (2003) use of a spiral to describe
37 the reinforcing cycles of control and collaboration in organizational governance.

46
47
48
49
50
51
52
53
54
55
56

57 While this class is rare (present in only 3% of the analysed figures), our review shows a recent
58 resurgence in the use of tridimensional spirals to represent paradox. For example, in their study of a
59
60

1
2
3 start-up that radically altered the music industry, Kassinis and Panayiotou (2017) use a helix to depict
4
5 the stability-change paradox. They urge the use of such tridimensional figures in capturing change
6
7 processes to overcome the limitations of language and of the more traditional, static visuals. They
8
9 argue (p. 158):

10
11
12
13 “The helix captures more powerfully the complexity and dynamism we seek to portray: through movement in a 3-
14
15 D plane, it exemplifies changing and offers a cognitive way out of the change-stability duality. It also holds the
16
17 potential of the ‘super-helix’ and the ‘ripple effect’, as a further enhancement of the basic model [...] More
18
19 importantly, the 3-D component of the helix illustrates the idea of ‘centrifugal structuring’ that Clegg et al. (2002:
20
21 495) describe, so that paradoxical tensions can be simultaneously held in suspension and act as a dynamic, creative
22
23 force, as they revolve around a structural pole.”
24
25

26 *Understanding the prevalence of these classes*

27
28
29 Our analysis revealed that these ‘visual semiotics’ have not been consistently or continuously used to
30
31 visualize paradoxes. Rather (see Table 3) some forms of representations tend to be prevalent (in
32
33 particular, classes #3 and #5) while others are rarely employed (e.g., classes #4 and #7 or even #8).
34
35 Also, while some sign categories are used constantly over time, others seem to go in and out of fashion
36
37 (see Figure 3a). For instance, the use of class #3 is consistently high while there was a spike in class
38
39 #1 signs between 2012 and 2016, followed by a recent decline. The opposite happened to class #5,
40
41 appearing in half of papers before 2012, declining in the following 5 years, before heightening in the
42
43 last period. Randomness may apply. The use of classes of signs varies depending on the purpose of
44
45 the picture (Figure 3b): when figures are meant to represent paradoxical phenomena, a broader range
46
47 of sign types is employed. By contrast, figures describing paradox dynamics tend almost exclusively
48
49 to use the circle and the linear arrow.

1
2
3
4
5
6
7 Looking at the appearance of an antinomic class of signs is also revealing. In general, there is a
8 prevalence of open over bounded, linear over recursive, and equilibrium over disequilibrium, in the
9 visual representation of paradox (Table 4). However, the picture is more nuanced: while
10 representations suggesting a degree of equilibrium are present in practically all papers, the ratio
11 between linear and recursive, and between open and bounded, is far more balanced.

18 19 **Discussion**

20
21
22
23 In this article we asked the broad question: How do visuals in paradox academic work address the
24 tension of convergence and divergence in paradox theorizing, focusing on (1) what do visual
25 representations in paradox academic work reveal about paradox and its assumptions and (2), what new
26 possibilities and areas of exploration does mapping the literature reveal? To answer these questions,
27 we approached visual representation as a semiotic activity that occurs alongside written texts and
28 draws on different categories of signs to produce and share meaning (Cobley & Jansz, 2010). More
29 specifically, we developed an original method for analysing the visual elements of the paradox
30 academic literature, akin to discourse analysis of written texts, based on the frequency of use of the
31 basic symbols that compose visual representations of paradoxes and their dynamics. Analysing the
32 meaning conveyed by these recurring symbols allowed us to advance a typology of eight classes of
33 visuals, organized around three sets of contrasting dualities or antinomies.
34
35
36
37
38
39
40
41
42
43
44
45
46
47
48

49 As shown in Table 3 (frequencies of appearance), our findings demonstrate that some assumptions and
50 ideas about what a paradox is and how actors respond to them are more prevalent than others. For
51 instance, class #3 (cyclical reproduction) is prevalent. This seems logical as interdependence and
52 persistence of opposition underlie the definition of paradox and are aligned with the notion of
53 circularity and cyclical reproduction. More broadly, the prevalence of classes that convey equilibrium
54
55
56
57
58
59
60

1
2
3 (particularly #1, #3, and #5) supports the critical view that paradox researchers tend to ‘tame’ paradox,
4
5
6 underrating the role of conflict and over-emphasizing synergy (Cunha & Putnam, 2019; Fairhurst,
7
8 2019). In fact, as shown in Figure 3a (evolution of classes), over time, the only class that increased in
9
10 frequency emphasizes equilibrium (class #5), while the only one that decreased emphasizes
11
12 disequilibrium (class #6). But even within a prevalent category of visuals, such as class #3, there is
13
14 ample space to explore different forms of dynamic circularity (Tsoukas & Cunha, 2017). New
15
16 questions might include: How can paradox create stuckedness (Hage, 2009)? Or how can paradoxes
17
18 generate irresistible forces of transformation? The study of these expressions of out-of-control circles
19
20 promises to offer new angles of the dysfunctions of paradox.
21
22
23
24

25
26 Our analysis also draws attention to the variety of visuals used by figures describing paradoxes versus
27
28 those unpacking paradox dynamics. As shown in Figure 3b (distribution of classes), figures that
29
30 unpack paradox dynamics tend to rely almost exclusively on two classes (class #3, cyclical, and class
31
32 #5, sequence). By contrast, figures describing paradoxes rely on a wider range of classes (class #1,
33
34 balanced; class #3, cyclical; class #5, sequence; and class #6, chaotic change). Broadening the sets of
35
36 visuals used beyond those that have become conventional may facilitate divergence in theoretical
37
38 ideas, as theorizing and visualizing go hand in hand (Ravasi, 2017). This is especially important for
39
40 exploring paradox dynamics (Pradies et al., 2021b; Jarzabkowski, Bednarek, Chalkias, & Cacciatori,
41
42 2022).
43
44
45
46

47
48 By employing a heuristic device (the antinomy-based classification) that is normatively exhaustive (it
49
50 covers all possible visual forms, regardless of their appearance in literature), we also identify
51
52 unexplored territories, showing which classes of visuals have been underused. For example, class #4
53
54 (oscillation) contains very little exemplars, even though visuals such as a pendulum or an unbalanced
55
56 scale could be used to capture important developments in paradox theory, like the asymmetrical
57
58
59
60

1
2
3 relationship of opposite poles and the need to ‘protect’ the weaker pole of a paradox (Huq, Reay, &
4 Chreim, 2017).
5
6

7
8
9 Our findings thus contribute to paradox theory in three main ways. First, we show that visual
10 representations constitute the lynchpin between convergent and divergent forces, allowing scholars to
11 simultaneously reinforce and challenge current understandings of paradox. Hence, we show that
12 examining the theoretical development of the field without paying specific attention to the visuals is
13 incomplete—analogous to analysing a speech act by focusing solely on the content of the
14 communication and ignoring the non-verbal elements (e.g., pauses, gestures, emphasis, etc.) that bring
15 meanings to life. Indeed, visuals reinforce the role of analytical discovery by positioning the
16 phenomenon under study, showing the reader what is figure and ground, and highlighting key
17 dynamics. But visuals also go beyond analytical discovery. Unlike written texts, which rely on a
18 discursive mode of communication, visuals operate in a representational mode (Kress & Van Leeuwen,
19 2020) that does not require lengthy description or detailed elaboration to articulate an idea. As such,
20 visuals facilitate an intuitive grasp of the ways in which researchers push the boundaries of extant
21 knowledge.
22
23
24
25
26
27
28
29
30
31
32
33
34
35
36
37
38
39

40 This is consistent with research on visual argumentation (Groarke, Palczewski, & Godden, 2016),
41 which suggests that visuals may open up previously closed sites of contestation (e.g., Sundaramurthy
42 & Lewis, 2003), challenge taken-for-granted assumptions (e.g., Lewis, 2000), and create “mind-
43 bombs” (DeLuca, 1999, p. 4) that significantly transform current understandings in a field (e.g.,
44 Jarzabkowski & Lê, 2017). In sum, visuals may directly call attention to those aspects of paradox that
45 are not explained by prior research, making novelty apparent within the context of the familiar. For
46 instance, the modified yin-yang in Gümüşay, Smets and Morris’ (2020) study of the first Islamic bank
47 in Germany captures dynamism in the context of equilibrium; the knot in Jarzabkowski and colleagues
48 (2022) orients attention to the multiple paradoxes that characterize grand challenges in an
49
50
51
52
53
54
55

3 interorganizational system; the two scales in Pradies' (2022) study of French veterinarians highlight
4 that any balancing act when navigating paradox entails finding dynamic equilibrium, not only between
5 responses but also between emotional traces.
6
7
8
9

10
11 Second, our visual analysis contributes a tool for scholars to theorize competing demands. We induced
12 three key antinomies, or dualities: equilibrium/disequilibrium, bounded/open, and recursive/linear. We
13 see these antinomies as defining the terrain along which tensions have been theorized; they constitute
14 the field's 'cardinal points' (see Figure 2), which represent the fundamental principles used to
15 categorize or understand the codes or messages in the paradox literature. The three sets of antinomies
16 are an important theorizing tool, enabling scholars to engage in disciplined imagination (Weick, 1989).
17 On the one hand, the antinomies themselves afford the consistent application of guidelines (i.e., the
18 'disciplined' part of the theorizing process), but the repository of visuals depicted invites scholars to
19 generate alternative perspectives (the 'imagination' part of the process).
20
21
22
23
24
25
26
27
28
29
30
31

32
33 Third, by mapping the frequency of visuals used in the literature in a typology of eight classes, we
34 contribute an understanding of the performative effect of visuals. Building on the premise that the
35 visual language used in research papers has the capacity to shape social reality (Austin, 1962), our work
36 suggests that, over time, researchers have relied on a limited number of classes, inadvertently producing
37 recurrent conceptualizations of paradox that have shaped subsequent debate in the field and cemented
38 certain assumptions. Paradox visuals have thus recursively influenced the social phenomena they
39 purportedly capture and communicate (Marti & Gond, 2018).
40
41
42
43
44
45
46
47
48
49

50 This echoes the current literature on the performativity of theories, which focuses on the processes
51 through which theories shape the social structures and practices they are supposed to describe
52 (D'Adderio & Pollock, 2014; Marti & Gond, 2018). Yet we reveal one additional process that leads to
53 path dependence and self-fulfilment of theories: the surreptitious translation of ideas from older to
54 newer theories. If traditional management theories are equilibrium based, aimed at describing relations
55
56
57
58
59
60

1
2
3 between stable variables, paradox theory is process- and recursivity-based, aimed at examining the
4 mutual constitution of action and structure, of phenomena and response, of imagination and materiality
5
6 (Hernes & Bakken, 2003). Nonetheless, our analysis shows that assumptions of linearity and of one-
7
8 directional causal relationship are persistently conveyed in paradox theorizing through unambiguous
9
10 arrows and boxes. Similarly, the idea of equilibrium and status maintenance is conveyed by the
11
12 continued use of symmetrical, well-ordered graphic representations. Thus, some assumptions related
13
14 to the very paradigms that paradox theory is aiming to challenge are ironically projected through the
15
16 sensegiving effects of visuals.
17
18
19
20
21
22

23 Being mindful about performativity might encourage scholars to explore uncharted territories
24
25 purposefully, broadening the repertoire of paradox visuals. In line with the principle of requisite
26
27 variety, we argue that a complicated phenomenon, such as paradox, requires a commensurately varied
28
29 repertoire of representing concepts because “it takes richness to grasp richness” (Weick, 2007, p. 16).
30
31 We therefore open an “arena for performance” (Quattrone et al., 2021, p. 1205) in that we invite
32
33 reflexivity on what is visible and invisible in current paradox visualizations. For example, the little
34
35 visibility of visuals, such as a pendulum or an unbalanced scale (class #4), invites us to explore the
36
37 asymmetrical relationship of opposite poles (Cunha & Putnam, 2019). Indeed, converging towards
38
39 familiar symbols (e.g., circles and loops), at the expense of introducing divergent ones (e.g., pendulum,
40
41 zigzags, steps, and clouds), fails to match the complexity of what we seek to explain, with the risk of
42
43 producing visuals that oversimplify the ideas argued in written texts.
44
45
46
47
48

49 Additionally, our findings show that even if the use of complex, realistic symbols, and images (e.g.,
50
51 bridges, clouds, cliffs, etc.) is not as widespread as the use of simpler graphic signs, it is still quite
52
53 significant. Visual metaphors are indeed a powerful tool for theorizing (Cornelissen, 2006; Weick
54
55 1989) because they “force us to make *semantic leaps*” (Cornelissen, 2006, p. 1584). This facilitates the
56
57 emergence of new meanings and insights thanks to the juxtaposition of ideas from different domains.
58
59
60

1
2
3 Visual metaphors act as analogies, making “abstract subjects comprehensible” and “giv[ing] the
4 researcher permission to focus on the relevant part of the problem, to abstract out other parts” (Ketokivi,
5 Mantere, & Cornelissen, 2017, p. 237). Our work raises questions about how visual metaphors count
6 in paradox theorizing. It also invites scholars to consider other forms of visualization, such as the sailing
7 visuals used by Lê and Pradies (2022) to unpack improvisation when navigating paradox in stormy
8 conditions, or the African symbols and their relation to paradox theorizing explored by Koli and Lê
9 (2022). The introduction of more complex imagery could also allow scholars to transcend the three
10 antinomies.

22

23 **Conclusion**

24
25 Our paper encourages the community of paradox scholars to be as imaginative as possible in addressing
26 paradoxes visually. Along with the abstract and the contribution, we need to pay particular attention to
27 visual images because they may be the strongest messages we send to our audience. In sum our paper
28 invites discussion enriching representation of paradox, and thus opens multiple avenues for future
29 research. First, while our paper focuses on single basic visual elements of a figure, it may be that when
30 signs are combined, they reveal aspects of paradox that each sign alone does not. We see this as the
31 potential paradoxical visual nature of a single figure; that is, separately, two or more signs in the same
32 figure might appear disconnected, while together they convey novel elements of paradox. Second, our
33 analysis has explored visuals across different types of papers (e.g., empirical vs. theoretical) and figures
34 (e.g., figures visualizing paradox description or paradox dynamics); however, other dimensions, such
35 as the type of paradox being discussed, the level of analysis (e.g., individual, team, organization – and
36 interactions between them), or the number of poles at play, could be investigated. Future research could
37 also refine analysis further by looking at these dimensions. Third, our work addresses the
38 (in)commensurability of paradox. By using a two-by- two-by-two device, boundaries are created that
39 may suggest that expressions of paradox are relatively stable and commensurate. Yet, tensions are
40 dynamic and can evolve and metamorphose, exposing different meanings at different levels and time

3 scales (Jarzabkowski et al., 2013), or result in cascading effects (Gilbert, Michaud, Bentein, Dubois, &
4 Bédard, 2018). In essence, visualization is a way of seeing (Berger, 1972) but as scholars continue to
5
6 (re)produce visuals, one must never forget that a way of seeing is also a way of not seeing.

Figure 1. Data structure

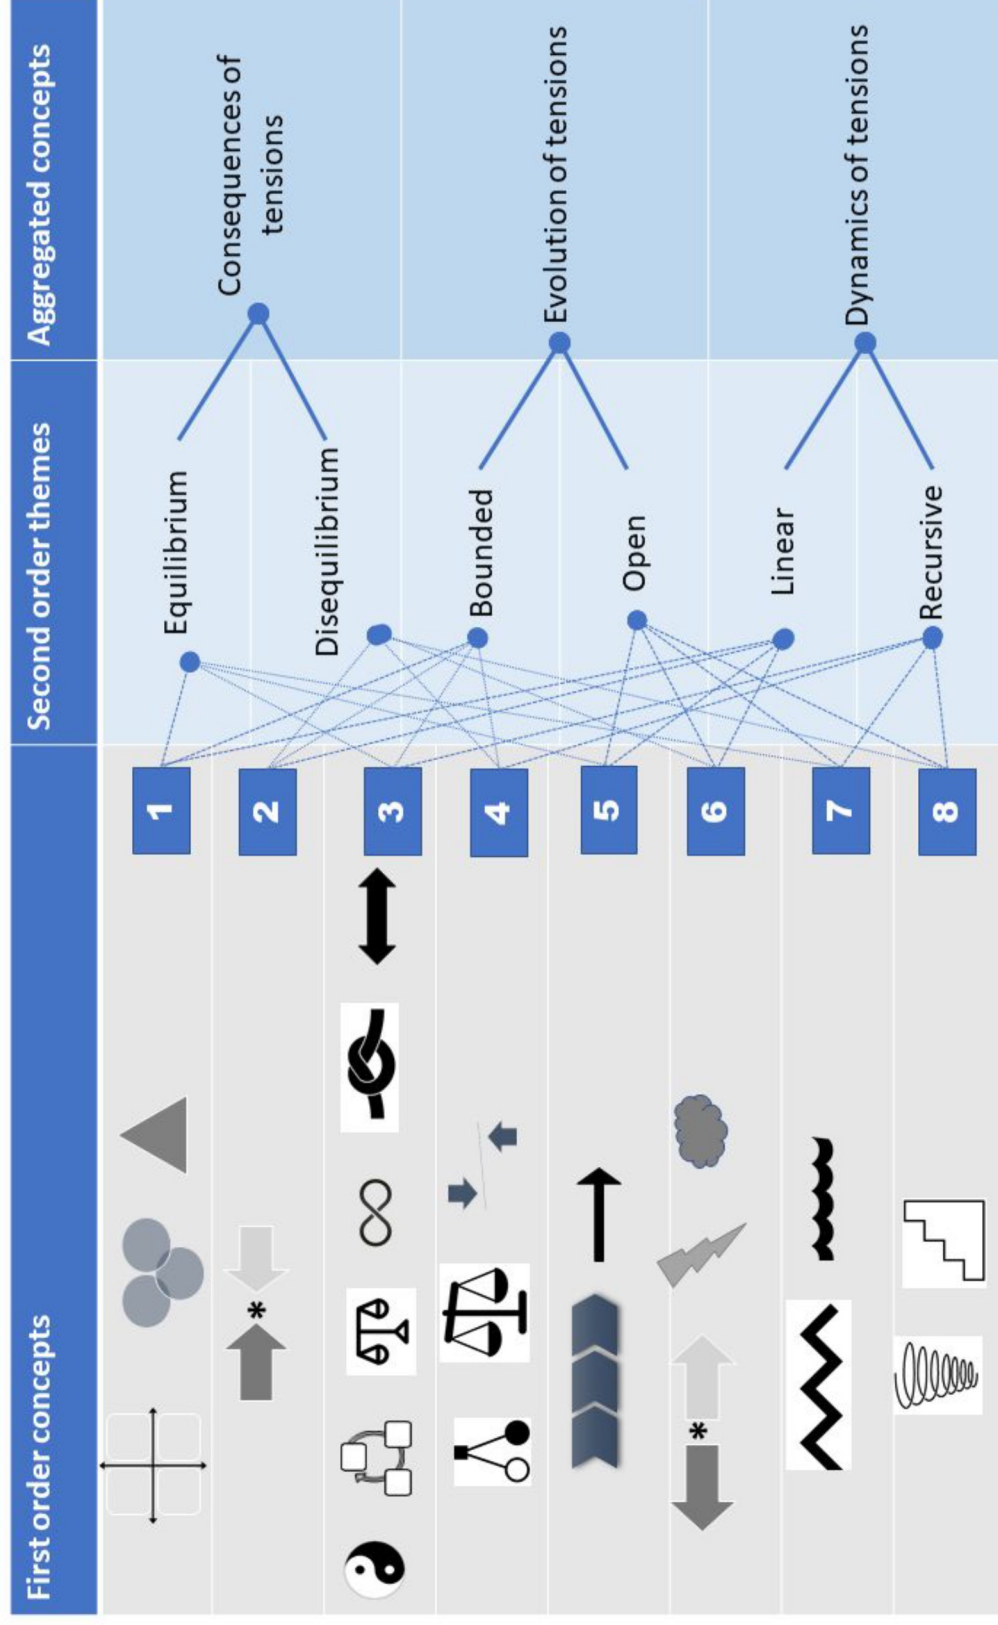

Figure 2. Classification device

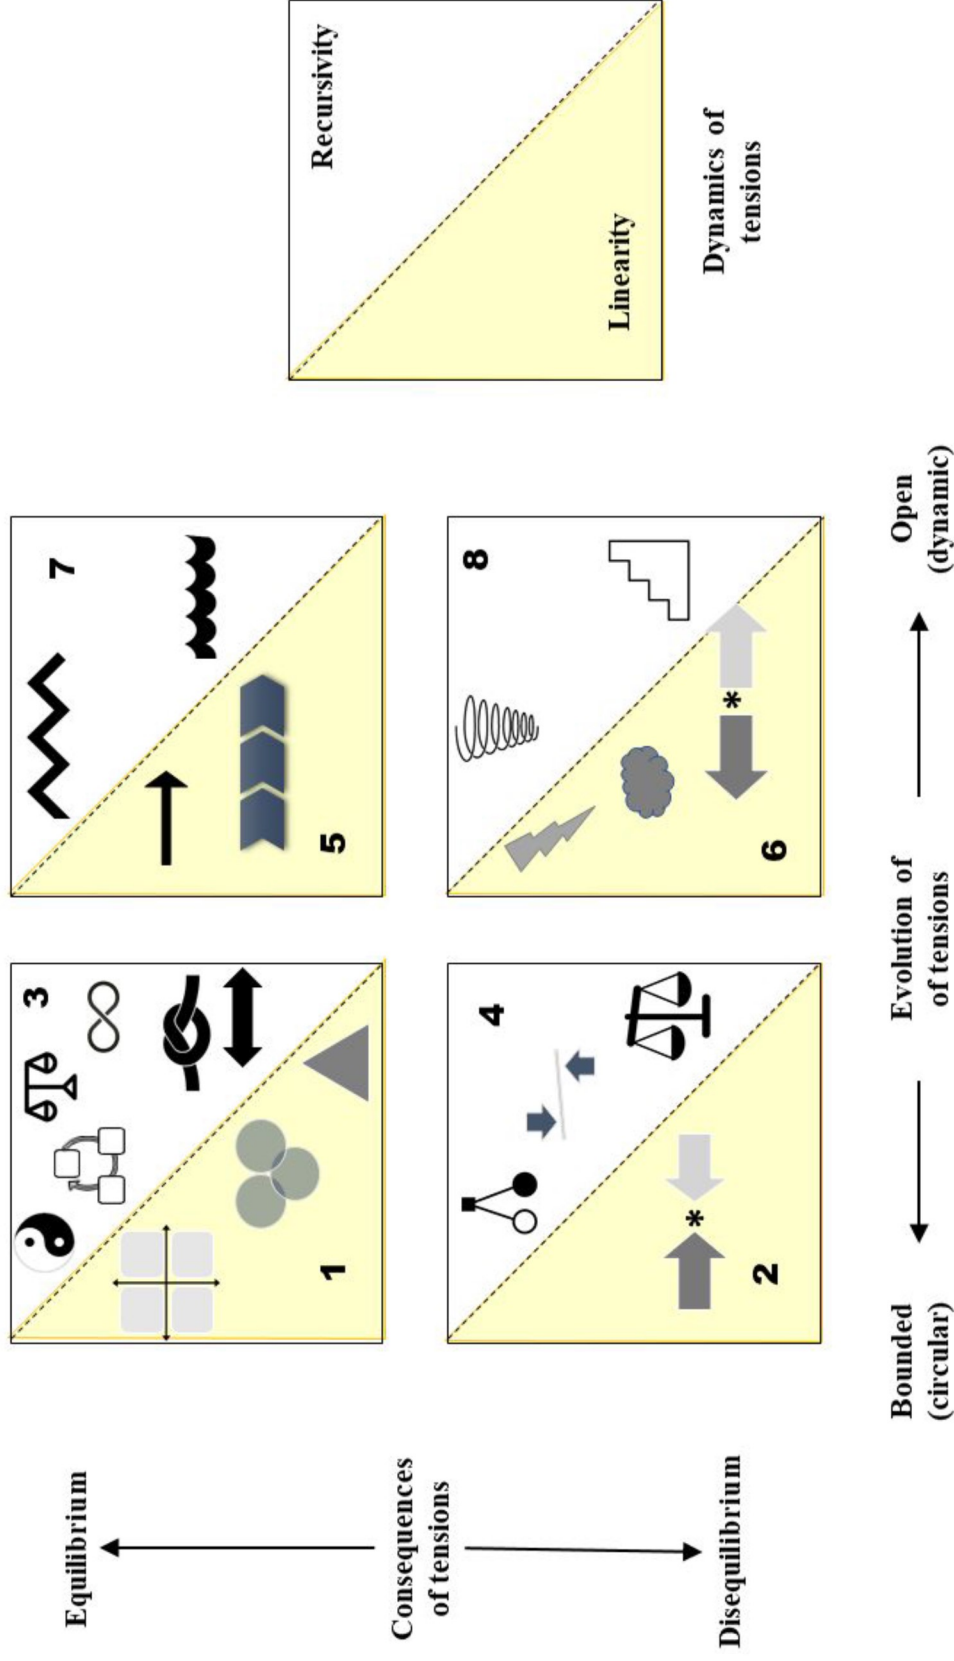

Figure 3a. Evolution of classes over time

Figure 3b. Distribution of classes between visuals that represent paradox description and paradox dynamics

Table 1. Definitions of antinomies

EQUILIBRIUM Balance and symmetry between opposites, leading to stable outcomes	↔	DISEQUILIBRIUM Unbalance and asymmetry between opposites, leading to unstable outcomes
OPEN A process that is divergent, with indeterminate outcomes and without a defined end, or a system which boundaries are not set	↔	BOUNDED A process that is convergent, with a predictable end, or a system which is self-contained, well-bound and operating within strict boundaries
LINEAR Sequence of events that progresses in a single direction	↔	RECURSIVE A process that iteratively loops into itself, leading to virtuous or vicious cycles

Table 2. Basic signs used in the visual grammar employed to describe paradox in the literature

CLASSIFICATION	Basic forms	Metaphorical images	Notes
Bounded Linear Equilibrium	Opposition (Cartesian diagram); Overlapping circles; Triangles	Cliff; Mirror images	The visual symbol suggest a balanced, static relationship between different elements/forces, which are in symmetry/equilibrium
1			
Bounded Linear			The visual symbol suggest a simple (measurable/predictable) relationship between two forces that are in direct opposition, creating at best a precarious balance maintained through struggle
2	Convergence		
Dis-equilibrium			
	Bidirectional arrows; Interconnected elements; Cycle; Knot; Interweaving elements; Loop	Ying & Yang; Janus; Weave; Balanced scale	The visual symbol suggest a recursive/iterative relation between elements which outcomes are stable and predictable (stability through cyclical reproduction)
3			
Bounded Recursive Equilibrium	Counterbalancing forces	Pendulum; Unbalanced Scale	The visual symbol suggests a recursive relationship between two elements, characterized by trade-offs that maintain the system in disequilibrium (any balance is only temporary)
4			
Open Linear Equilibrium	Arrow; Sequence	Bridge	The visual symbol suggests a sequential, continuous transformation that has no specified end but that does not imply contrast
5			
Open Linear			The visual symbol suggests a sequential, continuous transformation that has no specified end and that produces an instability in the system
6	Divergent lines or arrows	Scribble; Cloud; Thunder	
Open Recursive Equilibrium	(Figure/Background graphic) Zig zag	Wave	The recursive relation between element leads to continuous transformation that takes place in the context of a preserved equilibrium
7			
Open Recursive Dis-equilibrium	Spiral; Helix; Escalation	Cascade	The visual suggests a recursive relation between element leads to divergent transformation that disrupts/transform the existing system
8			

Table 3. Frequencies of appearance of a class across the 266 figures analyzed

Classification	Basic forms	Occurrences	% <i>(across the 266 figures analysed)</i>
1 Bounded Linear Equilibrium	Opposition (Cartesian diagram); Overlapping circles; Triangles	73	27%
2 Bounded Linear Dis-equilibrium	Convergence	30	11%
3 Bounded Recursive Equilibrium	Bidirectional arrows; Interconnected elements; Cycle; Knot; Interweaving elements; Loop	156	59%
4 Bounded Recursive Dis-equilibrium	Counterbalancing forces	3	1%
5 Open Linear Equilibrium	Arrow; Sequence	104	39%
6 Open Linear Dis-equilibrium	Divergent lines or arrows	60	23%
7 Open Recursive Equilibrium	(Figure/Background graphic) Zig zag	2	1%
8 Open Recursive Dis-equilibrium	Spiral; Helix; Escalation	7	3%

Table 4. Count of signs in each antinomy

	Consequences				Evolution			Dynamics	
	Equilibrium	Disequilibrium	Bounded	Open	Linear	Recursive			
Overall									
(Signs: n = 435)	n	n	n	n	n	n			
	335	100	262	173	267	168			
	77%	23%	60%	40%	61%	39%			
Empirical vs. conceptual papers									
Empirical only	n	n	n	n	n	n			
(Signs n = 244)	191	53	141	103	145	99			
	78%	22%	58%	42%	59%	41%

Author biographies

Camille Pradies is Associate Professor of Management at EDHEC Business School, France. Her research focuses on paradoxes and emotions such as ambivalence at the individual and group levels and on the organizational and institutional conditions that influence them.

Miguel Pina e Cunha is the Fundação Amélia de Mello Professor at Nova School of Business and Economics, Universidade Nova de Lisboa. He received his Ph.D. in management from Tilburg University. His research focuses on organization as process and paradox.

Arménio Rego is a Professor at the Católica Porto Business School, Universidade Católica Portuguesa, and member of the Business Research Unit, Instituto Universitário de Lisboa (ISCTE-IUL). His research deals mainly with leadership and positive organizational scholarship.

Marco Berti is Senior Lecturer in Management at UTS Business School, University of Technology Sydney. He received his Ph.D. in management from the University of Technology Sydney. His research focuses on organizational paradoxes and tensions, critical themes, and the role of power and discourse in organizations.

Andrea Tunarosa is Assistant Professor of Management at the Sykes College of Business, The University of Tampa. Her research focuses on how actors harness cultural resources to influence collective-level processes associated with sensemaking, coordination, and creativity.

Stewart Clegg is currently Professor of Project Management at the University of Sydney. He is also Emeritus Distinguished Professor in Management at UTS Business School, University of Technology Sydney, with virtual visiting appointments at Nova School of Business & Economics and Stavanger Business School. He received his Ph.D. in management from Bradford University and also holds doctoral degrees from Umeå and the University of Technology Sydney. His research is substantively wide-ranging but usually centred on paradoxes and power relations.
